Abstract. In this paper, by using the matrix representation of generalized bicomplex numbers, we have defined the homothetic motions on some hypersurfaces in four dimensional generalized linear space \( \mathbb{R}^{4}_{\alpha\beta} \). Also, for some special cases we have given some examples of homothetic motions in \( \mathbb{R}^4 \) and \( \mathbb{R}^4_2 \) and obtained some rotational matrices, too. Therefore, we have investigated some applications about kinematics of generalized bicomplex numbers.

Key words: Bicomplex number, Generalized Bicomplex numbers, Homothetic motion.

1. Introduction

In the middle of the 1800s, several mathematicians discussed the problem of whether a number system extended the field of complex numbers. In 1843, Sir William Rowan Hamilton defined a number system which is called quaternions in four dimensional space. Although quaternions and complex numbers have a lot of similar properties, quaternions are not commutative with respect to multiplication. So, in 1892, a new number system called bicomplex numbers was discovered by Corrado Segre [13]. Unlike quaternions, bicomplex numbers are commutative four dimensional real algebra.
The set of bicomplex numbers denoted by $\mathbb{C}_2$ is defined as:

$\mathbb{C}_2 = \{x = x_1 1 + x_2 i + x_3 j + x_4 ij : i^2 = -1, j^2 = -1, ij = ji, x_k \in \mathbb{R}, 1 \leq k \leq 4\}$.

Any $x$ bicomplex number can be rewritten as $x = z_1 + jz_2$, where $z_1 = x_1 + ix_2$ and $z_2 = x_3 + ix_4$ are complex numbers and $j$ is a different imaginer unit from the imaginer unit $i$ satisfied $j^2 = -1$ and $ij = ji$. Hence, we can perceive a bicomplex number as a complex number whose components are complex numbers.

There are some applications of bicomplex numbers on the algebra, geometry and analysis. A first theory of differentiability in $\mathbb{C}_2$ was developed by Price in [12]. Özkaldi Karakuş and Kahraman Aksoyak defined generalized bicomplex numbers and gave some algebraic properties. Also, they showed that some hypersurfaces in four dimensional generalized linear space are Lie groups by using generalized bicomplex number product and obtained Lie algebras of these Lie groups [10].

Kabadayı and Yaylı defined the homothetic motions with the help of bicomplex numbers in $\mathbb{R}^4$ [5]. They showed that this homothetic motion under some conditions holds all of the properties in [14], [15]. Alkaya studied the homothetic motion with bicomplex numbers in $\mathbb{R}^4$ and $\mathbb{R}^2$ [1].

In this paper, by using the matrix representation of generalized bicomplex numbers, we shall define the homothetic motions on some hypersurfaces in four dimensional generalized linear space $\mathbb{R}^4_{\alpha\beta}$. Also, for some special cases we shall give some examples of homothetic motions in $\mathbb{R}^4$ and $\mathbb{R}^2$ and obtain some rotational matrices, too. Therefore, we shall investigate some applications about kinematics of generalized bicomplex numbers.

2. Preliminaries

In this section we give some basic concepts about generalized bicomplex numbers defined by Özkaldi Karakuş and Kahraman Aksoyak [10].

A generalized bicomplex number $x$ is defined as follows:

$$x = x_1 1 + x_2 i + x_3 j + x_4 ij,$$

where $x_k$ for $1 \leq k \leq 4$ are real numbers and the basis $\{1, i, j, ij\}$ holds $i^2 = -\alpha$, $j^2 = -\beta$, $(ij)^2 = \alpha\beta$, $ij = ji$, $\alpha, \beta \in \mathbb{R}$. The set of generalized bicomplex numbers is denoted by $\mathbb{C}_{\alpha\beta}$. For any two generalized bicomplex numbers $x = x_1 + x_2 i + x_3 j + x_4 ij$ and $y = y_1 + y_2 i + y_3 j + y_4 ij$, addition and multiplication are as follows:

$$x + y = (x_1 + y_1) + (x_2 + y_2) i + (x_3 + y_3) j + (x_4 + y_4) ij,$$

and the scalar multiplication of an element in $\mathbb{C}_{\alpha\beta}$ by a real number $c$ is as:

$$cx = cx_1 1 + cx_2 i + cx_3 j + cx_4 ij.$$
Hence, by means of these elementary arithmetic operations on \( C_{\alpha\beta} \), we have two important results. \( C_{\alpha\beta} \) is a four dimensional real vector space with respect to addition and scalar multiplication and it is a commutative real algebra according to generalized bicomplex number product.

Let us consider the following set of matrices

\[
Q_{\alpha\beta} = \left\{ M_z = \begin{pmatrix} x_1 & -\alpha x_2 & -\beta x_3 & \alpha\beta x_4 \\ x_2 & x_1 & -\beta x_4 & -\beta x_3 \\ x_3 & -\alpha x_4 & x_1 & -\alpha x_2 \\ x_4 & x_3 & x_2 & x_1 \end{pmatrix} : x_i \in \mathbb{R}, 1 \leq i \leq 4 \right\},
\]

where the set \( Q_{\alpha\beta} \) is a vector space with matrix addition and scalar matrix product and it is an algebra together with matrix product. The algebras \( C_{\alpha\beta} \) and \( Q_{\alpha\beta} \) are isomorphic. The isomorphism between two algebras is defined as:

\[
h : C_{\alpha\beta} \rightarrow Q_{\alpha\beta},
\]

\[
h (x_1 1 + x_2 i + x_3 j + x_4 ij) = \begin{pmatrix} x_1 & -\alpha x_2 & -\beta x_3 & \alpha\beta x_4 \\ x_2 & x_1 & -\beta x_4 & -\beta x_3 \\ x_3 & -\alpha x_4 & x_1 & -\alpha x_2 \\ x_4 & x_3 & x_2 & x_1 \end{pmatrix}.
\]

With the help of this isomorphism, any generalized bicomplex number in \( C_{\alpha\beta} \) can be represent by a matrix in \( Q_{\alpha\beta} \). Moreover, it is possible to express the generalized bicomplex number product which has been given by (2.1) by matrix product, that is,

\[
x \cdot y = \begin{pmatrix} x_1 & -\alpha x_2 & -\beta x_3 & \alpha\beta x_4 \\ x_2 & x_1 & -\beta x_4 & -\beta x_3 \\ x_3 & -\alpha x_4 & x_1 & -\alpha x_2 \\ x_4 & x_3 & x_2 & x_1 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{pmatrix}.
\]

A generalized bicomplex number can be rewritten as \( x = (x_1 + x_2 i) + (x_3 + x_4 i) j \). There are three kinds of conjugations for generalized bicomplex numbers. They are given as follows:

\[
x^{t_1} = [(x_1 + x_2 i) + (x_3 + x_4 i) j]^{t_1} = (x_1 - x_2 i) + (x_3 - x_4 i) j,
\]

\[
x^{t_2} = [(x_1 + x_2 i) + (x_3 + x_4 i) j]^{t_2} = (x_1 + x_2 i) - (x_3 + x_4 i) j,
\]

\[
x^{t_3} = [(x_1 + x_2 i) + (x_3 + x_4 i) j]^{t_3} = (x_1 - x_2 i) - (x_3 - x_4 i) j,
\]

where \( x^{t_1}, x^{t_2} \) and \( x^{t_3} \) denote the conjugations of \( x \) with respect to \( i, j \) and both \( i \) and \( j \), respectively. Also we can compute

\[
x \cdot x^{t_1} = (x_1^2 + \alpha x_2^2 - \beta x_3^2 - \alpha\beta x_4^2) + 2(x_1 x_3 + \alpha x_2 x_4) j,
\]

\[
x \cdot x^{t_2} = (x_1^2 - \alpha x_2^2 + \beta x_3^2 - \alpha\beta x_4^2) + 2(x_1 x_2 + \beta x_3 x_4) i,
\]

\[
x \cdot x^{t_3} = (x_1^2 + \alpha x_2^2 + \beta x_3^2 + \alpha\beta x_4^2) + 2(x_1 x_4 - x_2 x_3) ij.
\]
3. One Parameter Homothetic Motion

Let the fixed space and the moving space be $R_0$ and $R$, respectively. The one-parameter homothetic motion of $R_0$ with respect to $R$ is denoted by $R_0/R$. This motion is obtained by the following transformation

$$\begin{bmatrix} X \\ 1 \end{bmatrix} = \begin{bmatrix} hA & C \\ 0 & 1 \end{bmatrix} \begin{bmatrix} X_0 \\ 1 \end{bmatrix},$$

or it can be expressed as

$$X = BX_0 + C,$$

(3.1)

in which $X_0$ and $X$ are the position vectors of the same point in $R_0$ and $R$, respectively and $B = hA$. Also, $h$, $A$ and $C$ are continuously differentiable functions depend on the real parameter $t$, where $h : I \subset \mathbb{R} \rightarrow \mathbb{R}$, $t \rightarrow h(t)$ is called homothetic scale of the motion, $A$ is a real quasi-orthogonal matrix that holds $A^T \varepsilon A = \varepsilon$ ($\varepsilon$ is a signature matrix according to metric), $C$ is the translation matrix. To avoid the case of affine transformation we suppose that $h$ is not constant and to avoid the cases of pure translation and pure rotation we also assume that $\frac{d(hA)}{dt} \neq 0$ and $\frac{dC}{dt} \neq 0$ [2].

4. Pole Points and Pole Curves of the Homothetic Motion

If we take the derivative of (3.1) with respect to $t$, we obtain the following equality

$$\dot{X} = \dot{B}X_0 + \dot{C} + B\dot{X}_0,$$

where $\dot{X}$ is the absolute velocity, $\dot{B}X_0 + \dot{C}$ is the sliding velocity and $B\dot{X}_0$ is the relative velocity of the point $X_0$. The points at which the sliding velocity of the motion vanishes at all time $t$ are called pole points of the motion in $R_0$. In that case, to determine the pole points of the motion, we solve the following equality

$$\dot{B}X_0 + \dot{C} = 0.$$

(4.1)

For more details see[2].

5. Homothetic Motions on Some Hypersurfaces via Generalized Bicomplex Numbers

In this section we have defined the homothetic motions on some hypersurfaces at $\mathbb{R}^{4,3}_\alpha$ with the help of generalized bicomplex numbers and given some examples about the homothetic motions.
5.1. Homothetic Motion on Hypersurface $M_1$

Let us consider the hypersurface $M_1$ as follows:

$$M_1 = \{ x = (x_1, x_2, x_3, x_4) \in \mathbb{R}^{4}_{\alpha\beta} : x_1 x_3 + \alpha x_2 x_4 = 0, \ x \neq 0 \} .$$

By using generalized bicomplex numbers, $M_1$ can be rewritten as:

$$M_1 = \{ x = x_1 + x_2 i + x_3 j + x_4 ij \in \mathbb{R}^{4}_{\alpha\beta} : x_1 x_3 + \alpha x_2 x_4 = 0, \ x \neq 0 \} ,$$

or the hypersurface $M_1$ can be expressed by using the matrix representation of generalized bicomplex numbers

$$\tilde{M}_1 = \left\{ M_x = \begin{pmatrix} x_1 & -\alpha x_2 & -\beta x_3 & \alpha \beta x_4 \\ x_2 & x_1 & -\beta x_4 & -\beta x_3 \\ x_3 & -\alpha x_4 & x_1 & -\alpha x_2 \\ x_4 & x_3 & x_2 & x_1 \end{pmatrix} : x_1 x_3 + \alpha x_2 x_4 = 0, \ x \neq 0 \right\} ,$$

where $M_x$ is the matrix representation of generalized bicomplex number $x$. The metric on hypersurface $M_1$ is defined by $g_1(x, x) = x \cdot x^t_1 = x_1^2 + \alpha x_2^2 - \beta x_3^2 - \alpha \beta x_4^2$ and the norm of any element $x$ on $M_1$ is defined by $\| x \| = \sqrt{|g_1(x, x)|} = \sqrt{|x \cdot x^{t_1}|}$. This metric is Riemannian or pseudo-Riemannian metric on four dimensional generalized linear space $\mathbb{R}^{4}_{\alpha\beta}$ and for some special cases, it coincides with four dimensional Euclidean space $\mathbb{R}^4$ or four dimensional pseudo-Euclidean space $\mathbb{R}^4_{2}$.

**Proposition 5.1.** There are following properties about the norm on the hypersurface $M_1$.

i) For $x, y \in M_1$, $\| x \cdot y \| = \| x \| \| y \| ,$

ii) $\| x \|^4 = \det (M_x)$.

**Proof.** These properties can be easily seen with direct calculations. \( \square \)

**Corollary 5.1.** A unit generalized bicomplex number on the hypersurface $M_1$ determines a rotation motion.

**Proof.** It is obvious from Proposition 5.1. \( \square \)

**Theorem 5.1.** $M_1$ is a commutative Lie group.

**Proof.** The proof can be found in [10]. \( \square \)

Let us denote the set of unit generalized bicomplex numbers on $M_1$ by $M_1^*$. $M_1^*$ is as:

$$M_1^* = \{ x \in M_1 : g_1(x, x) = 1 \}
= \{ x \in M_1 : x_1^2 + \alpha x_2^2 - \beta x_3^2 - \alpha \beta x_4^2 = 1 \} .$$
Theorem 5.2. $M_1^*$ is Lie subgroup of $M_1$.

Proof. The proof can be found in [10]. □

Let $\gamma$ be a curve on $M_1$. In that case, it can be expressed as

$$\gamma : I \subset \mathbb{R} \rightarrow M_1$$

$$t \rightarrow \gamma(t) = \gamma_1(t) + \gamma_2(t)i + \gamma_3(t)j + \gamma_4(t)k, \quad \gamma_1(t)\gamma_3(t) + \alpha\gamma_2(t)\gamma_4(t) = 0.$$  

Then the matrix $B$ corresponding to the curve $\gamma$ is obtained as follows:

$$(5.1) \quad B = M_{\gamma(t)} = \begin{bmatrix} \gamma_1(t) & -\alpha\gamma_2(t) & -\beta\gamma_3(t) & \alpha\beta\gamma_4(t) \\ \gamma_2(t) & \gamma_1(t) & -\beta\gamma_4(t) & -\beta\gamma_3(t) \\ \gamma_3(t) & -\alpha\gamma_4(t) & \gamma_1(t) & -\alpha\gamma_2(t) \\ \gamma_4(t) & \gamma_3(t) & \gamma_2(t) & \gamma_1(t) \end{bmatrix}.$$  

Now by using this matrix $B$, we can define the one parameter motion on $M_1$ at $\mathbb{R}_{\alpha,\beta}^4$.

Definition 5.1. Let $R_0$ and $R$ be the fixed space and the motional space at $\mathbb{R}_{\alpha,\beta}^4$. In that case, the one-parameter motion of $R_0$ with respect to $R$ is denoted by $R_0/R$. Then the one-parameter motion on $M_1$ is defined by

$$\begin{bmatrix} X \\ 1 \end{bmatrix} = \begin{bmatrix} B & C \\ 0 & 1 \end{bmatrix} \begin{bmatrix} X_0 \\ 1 \end{bmatrix},$$

or it can be expressed as

$$(5.2) \quad X = BX_0 + C,$$

where $B$ is the matrix associated with the curve $\gamma(t)$ on the hypersurface $M_1$, $C$ is the $4 \times 1$ real matrix depends on a real parameter $t$, $X$ and $X_0$ are the position vectors of any point at $\mathbb{R}_{\alpha,\beta}^4$ respectively in $R$ and $R_0$.

Theorem 5.3. The equation given by (5.2) determines a homothetic motion on $M_1$.

Proof. Since the curve $\gamma$ lies on $M_1$, it does not pass through the origin. So, the matrix given by (5.1) can be expressed as:

$$(5.3) \quad B = M_{\gamma(t)} = h \begin{bmatrix} \gamma_1(t) & -\alpha\gamma_2(t) & -\beta\gamma_3(t) & \alpha\beta\gamma_4(t) \\ \gamma_2(t) & \gamma_1(t) & -\beta\gamma_4(t) & -\beta\gamma_3(t) \\ \gamma_3(t) & -\alpha\gamma_4(t) & \gamma_1(t) & -\alpha\gamma_2(t) \\ \gamma_4(t) & \gamma_3(t) & \gamma_2(t) & \gamma_1(t) \end{bmatrix} = hA,$$

where $h : I \subset \mathbb{R} \rightarrow \mathbb{R}$, $t \rightarrow h(t) = \|\gamma(t)\| = \sqrt{\gamma_1^2 + \alpha\gamma_2^2 - \beta\gamma_3^2 - \alpha\beta\gamma_4^2}$. Because of $\gamma(t) \in M_1$, $\gamma_1(t)\gamma_3(t) + \alpha\gamma_2(t)\gamma_4(t) = 0$. By using this equality, we obtain that
the matrix \( A \) in (5.3) is a real quasi-orthogonal matrix. In that case it satisfies \( A^T \varepsilon A = \varepsilon \) and \( \det A = 1 \), where \( \varepsilon \) is the signature matrix corresponding to metric \( g_1 \) is as:

\[
\varepsilon = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & \alpha & 0 & 0 \\
0 & 0 & -\beta & 0 \\
0 & 0 & 0 & -\alpha \beta
\end{bmatrix}.
\]

Hence \( A, h \) and \( C \) are a real quasi-orthogonal matrix, the homothetic scale of the motion and the translation vector, respectively. So the equation (5.2) is a homothetic motion.

Remark 5.1. The norm of \( \gamma \in \mathbb{R}^4_{\alpha, \beta} \) is found as

\[
\| \gamma(t) \| = \sqrt{\gamma_1^2 + \alpha \gamma_2^2 - \beta \gamma_3^2 - \alpha \beta \gamma_4^2}.
\]

We assume that \( \gamma_1^2 + \alpha \gamma_2^2 - \beta \gamma_3^2 - \alpha \beta \gamma_4^2 > 0 \) in this paper.

Corollary 5.2. Let \( \gamma(t) \) be a curve on \( M_1^* \). Then one-parameter motion on \( M_1 \) given by (5.2) is a general motion consists of a rotation and a translation.

Proof. We assume that \( \gamma(t) \) is a curve on \( M_1^* \). Then \( \gamma_1^2 + \alpha \gamma_2^2 - \beta \gamma_3^2 - \alpha \beta \gamma_4^2 = 1 \). In that case the matrix \( B \) given by (5.1) becomes a real-quasi orthogonal matrix, that is, it satisfies \( B^T \varepsilon B = \varepsilon \) and \( \det B = 1 \). This completes the proof.

Theorem 5.4. Let \( \gamma(t) \) be a unit velocity curve and its tangent vector \( \dot{\gamma}(t) \) be on \( M_1 \). Then the derivative of the matrix \( B \) is a real quasi-orthogonal matrix.

Proof. We suppose that \( \gamma(t) \) be a unit velocity curve. Then \( \dot{\gamma}_1^2 + \alpha \dot{\gamma}_2^2 - \beta \dot{\gamma}_3^2 - \alpha \beta \dot{\gamma}_4^2 = 1 \). Also, since the tangent vector of \( \gamma \) is on \( M_1 \), it implies that \( \dot{\gamma}_1(t) \dot{\gamma}_3(t) + \alpha \dot{\gamma}_2(t) \dot{\gamma}_4(t) = 0 \). Thus \( \dot{B}^T \varepsilon \dot{B} = \varepsilon \) and \( \det \dot{B} = 1 \).

Theorem 5.5. Let \( \gamma(t) \) be a unit velocity curve and its tangent vector \( \dot{\gamma}(t) \) be on \( M_1 \). Then the motion is a regular motion and it is independent of \( h \).

Proof. From Theorem 5.4, \( \det \dot{B} = 1 \) and thus the value of \( \det \dot{B} \) is independent of \( h \).

Theorem 5.6. Let \( \gamma(t) \) be a unit velocity curve whose the position vector and tangent vector are on \( M_1 \). Then the pole points of the motion given by (5.2) are

\[
X_0 = -\dot{B}^{-1} \dot{C}.
\]

Proof. Since the position vector of the curve \( \gamma \) is on \( M_1 \), from Theorem 5.3, the equation (5.2) becomes a homothetic motion. Also, because of \( \gamma(t) \) is a unit velocity curve and \( \dot{\gamma}(t) \in M_1 \), from Theorem 5.4 \( \det \dot{B} = 1 \) and it implies that there is only one solution of the equation (4.1). Then the pole points of the motion given by (5.2) are obtained as \( X_0 = -\dot{B}^{-1} \dot{C} \).
Corollary 5.3. Let $\gamma(t)$ be a unit velocity curve whose the position vector and tangent vector are on $M_1$. The pole point associated with each $t$-instant in $R_0$ is the rotation by the matrix $B^{-1}$ of the speed vector of translation vector at the opposite direction $(-\dot{\gamma})$.

Proof. From Theorem 5.4, the matrix $\dot{B}$ is a real quasi-orthogonal matrix. Then the matrix $B^{-1}$ is quasi-orthogonal matrix, too. This completes the proof. □

Now we will give various examples of the homothetic motions on $M_1$ according to the situations of real numbers $\alpha$ and $\beta$.

Example 5.1. For $\alpha = \beta = 1$, $M_1$ becomes a hypersurface in $\mathbb{R}_4^2$. Let $\gamma : I \subset \mathbb{R} \rightarrow M_1 \subset \mathbb{R}_4^2$ be a curve given by

$$\gamma(t) = h(t) \left( \begin{array}{c} \cosh(at) \cos(bt) + \cosh(at) \sin(bt) i \\ - \sinh(at) \sin(bt) j + \sinh(at) \cos(bt) ij \end{array} \right),$$

where $a$ and $b$ are real numbers. By using (5.1) and (5.4), the matrix $B$ associated with the curve $\gamma$ becomes a homothetic matrix, where $h : I \subset \mathbb{R} \rightarrow \mathbb{R}$ is a homothetic scale. Also, if we take as $h(t) = 1$ in (5.4), then $\gamma$ is a curve on $M_1^*$ and the matrix $B$ determines a rotation matrix in $\mathbb{R}_4^2$. In (5.4), if we choose as $h(t) = 1$, $a = 0$ and $b = 1$, then we get

$$\gamma(t) = \cos t + i \sin t.$$

By using (5.1) and (5.5), we have the matrix $B$ as follows:

$$B = \begin{pmatrix} \cos t & -\sin t & 0 & 0 \\ \sin t & \cos t & 0 & 0 \\ 0 & 0 & \cos t & -\sin t \\ 0 & 0 & \sin t & \cos t \end{pmatrix},$$

where $B$ is a rotational matrix in $\mathbb{R}_4^2$. Since this curve given by (5.5) is unit speed curve and its tangent vector belongs to $M_1$, the derivation of the above matrix $B$ is a real quasi-orthogonal matrix, too. Then it is a rotational matrix in $\mathbb{R}_4^2$. Similarly, in (5.4) if we take as $h(t) = 1$, $a = 1$ and $b = 0$, then we get

$$\gamma(t) = \cosh t + ij \sinh t.$$

By using (5.1) and (5.6), we have the matrix $B$ as follows:

$$B = \begin{pmatrix} \cosh t & 0 & 0 & \sinh t \\ 0 & \cosh t & -\sinh t & 0 \\ 0 & -\sinh t & \cosh t & 0 \\ \sinh t & 0 & 0 & \cosh t \end{pmatrix},$$

where $B$ is a rotational matrix in $\mathbb{R}_4^2$.

Example 5.2. For $\alpha = 1$, $\beta = -1$, $M_1$ is a hypersurface in $\mathbb{R}^4$. Let $\gamma : I \subset \mathbb{R} \rightarrow M_1 \subset \mathbb{R}^4$ be a curve given by

$$\gamma(t) = h(t) \left( \begin{array}{c} \cos(at) \cos(bt) + \cos(at) \sin(bt) i \\ - \sin(at) \sin(bt) j + \sin(at) \cos(bt) ij \end{array} \right),$$

where $a$ and $b$ are real numbers.
where \( a \) and \( b \) are real numbers. By using (5.1) and (5.7), the matrix representation of the curve \( \gamma \) is a homothetic matrix, in here \( h : I \subset \mathbb{R} \to \mathbb{R} \) is a homothetic scale. Also, for \( h(t) = 1 \), \( \gamma \) becomes a spherical curve on \( M_1 \), that is, \( \gamma(t) \in \mathbb{M}_1 = M_1 \cap S^4 \). The matrix representation of it is a rotation matrix in \( \mathbb{R}^4 \). Even, if we take as \( h(t) = 1, a = 0, b = 1 \), then

\[
\gamma(t) = \cos t + i \sin t.
\]

From (5.1) and (5.8), by determining the matrix representation of the above curve, we obtain

\[
B = \begin{pmatrix}
\cos t & -\sin t & 0 & 0 \\
\sin t & \cos t & 0 & 0 \\
0 & 0 & \cos t & -\sin t \\
0 & 0 & \sin t & \cos t
\end{pmatrix}.
\]

This matrix is a general rotational matrix in \( \mathbb{R}^4 \) which is defined by Moore [8]. Also, from Theorem 5.4, \( B \) is a real orthogonal matrix, too.

**Example 5.3.** For \( \alpha = \beta = -1 \), the hypersurface \( M_1 \) lies in \( \mathbb{R}^4_2 \) and the following curve lies on \( M_1 \)

\[
\gamma(t) = h(t) \begin{pmatrix}
\cosh (at) \cosh (bt) + \cosh (at) \sinh (bt) i \\
+ \sinh (at) \sinh (bt) j + \cosh (at) \sinh (bt) i j
\end{pmatrix},
\]

in which \( a \) and \( b \) are real numbers. From (5.1) and (5.9), the matrix \( B \) according to the curve \( \gamma \) is a homothetic matrix, where \( h : I \subset \mathbb{R} \to \mathbb{R} \) is a homothetic scale. Also, if we take as \( h(t) = 1 \), then \( \gamma \) lies on \( M_1 \) and the matrix \( B \) gives a rotation matrix in \( \mathbb{R}^4_2 \).

### 5.2. Homothetic Motion on Hypersurface \( M_2 \)

Let us consider the hypersurface \( M_2 \), as follows:

\[
M_2 = \{ x = (x_1, x_2, x_3, x_4) \in \mathbb{R}^4_{\alpha, \beta} : x_1x_2 + \beta x_3 x_4 = 0, \ x \neq 0 \}.
\]

By using the generalized bicomplex numbers, \( M_2 \) can be rewritten as:

\[
M_2 = \{ x = x_1 + x_2 i + x_3 j + x_4 ij \in \mathbb{R}^4_{\alpha, \beta} : x_1x_2 + \beta x_3 x_4 = 0, \ x \neq 0 \},
\]

or the hypersurface \( M_2 \) can be expressed by using the matrix representation of generalized bicomplex numbers

\[
\tilde{M}_2 = \{ M_x = \begin{pmatrix}
x_1 & -\alpha x_2 & -\beta x_3 & \alpha \beta x_4 \\
x_2 & x_1 & -\beta x_4 & -\beta x_3 \\
x_3 & -\alpha x_4 & x_1 & -\alpha x_2 \\
x_4 & x_3 & x_2 & x_1
\end{pmatrix} : x_1x_2 + \beta x_3 x_4 = 0, \ x \neq 0 \},
\]

where \( M_x \) is the matrix representation of the generalized bicomplex number \( x \) on \( M_2 \). The metric on hypersurface \( M_2 \) is defined by \( g_2(x, x) = x \cdot x^{t_2} = x_1^2 - \alpha x_2^2 + \beta x_3^2 - \alpha \beta x_4^2 \) and the norm of any element \( x \) on \( M_2 \) is given by \( \|x\| = \sqrt{g_2(x, x)} = \sqrt{|x \cdot x^{t_2}|} \). This metric is Riemannian or pseudo-Riemannian metric on four dimensional generalized linear space \( \mathbb{R}^4_{\alpha, \beta} \) and for some special cases, it coincides with four dimensional Euclidean space \( \mathbb{R}^4 \) or four dimensional pseudo-Euclidean space \( \mathbb{R}^4_2 \).
Proposition 5.2. There are following properties about the norm on the hypersurface \( M_2 \).

i) For \( x, y \in M_2 \), \( \| x \cdot y \| = \| x \| \| y \| \),

ii) \( \| x \|^4 = \det (M_x) \).

Proof. These properties can be easily seen with directly calculations.

Corollary 5.4. A unit generalized bicomplex number on the hypersurface \( M_2 \) determines a rotation motion.

Proof. It is obvious from Proposition 5.2.

Theorem 5.7. \( M_2 \) is a commutative Lie group.

Proof. The proof can be found in \([10]\).

Let us denote the set of unit generalized bicomplex number on \( M_2 \) by \( M_2^* \). \( M_2^* \) is given as:

\[
M_2^* = \{ x \in M_2 : g_2 (x, x) = 1 \} = \{ x \in M_2 : x_1^2 - \alpha x_2^2 + \beta x_3^2 - \alpha \beta x_4^2 = 1 \}.
\]

Theorem 5.8. \( M_2^* \) is Lie subgroup of \( M_2 \).

Proof. The proof can be found in \([10]\).

Let \( \gamma \) be a curve on \( M_2 \). In that case, it can be expressed as:

\[
\gamma : I \subset \mathbb{R} \rightarrow M_2
\]

\[
t \rightarrow \gamma(t) = \gamma_1(t) + \gamma_2(t)i + \gamma_3(t)j + \gamma_4(t)ij, \quad \gamma_1(t)\gamma_2(t) + \beta \gamma_3(t)\gamma_4(t) = 0.
\]

Then the matrix \( B \) corresponding to the curve \( \gamma \) is given as follows:

\[
B = M_{\gamma(t)} = \begin{bmatrix}
\gamma_1(t) & -\alpha \gamma_2(t) & -\beta \gamma_3(t) & \alpha \beta \gamma_4(t) \\
\gamma_2(t) & \gamma_1(t) & -\beta \gamma_4(t) & -\beta \gamma_3(t) \\
\gamma_3(t) & -\alpha \gamma_4(t) & \gamma_1(t) & -\alpha \gamma_2(t) \\
\gamma_4(t) & \gamma_3(t) & \gamma_2(t) & \gamma_1(t)
\end{bmatrix}.
\]

Now by using this matrix \( B \), we can define the one parameter motion on \( M_2 \) at \( \mathbb{R}_0^4 \).

Definition 5.2. Let \( R_0 \) and \( R \) be the fixed space and the motional space at \( \mathbb{R}_0^4 \). In that case, the one-parameter motion of \( R_0 \) with respect to \( R \) is denoted by \( R_0/R \). Then the one-parameter motion on \( M_2 \) is given by

\[
\begin{bmatrix}
X \\
1
\end{bmatrix} = \begin{bmatrix}
B & C \\
0 & 1
\end{bmatrix} \begin{bmatrix}
X_0 \\
1
\end{bmatrix},
\]
or it can be expressed as

\[ X = BX_0 + C, \]

where \( B \) is the matrix associated with the curve \( \gamma(t) \) on the hypersurface \( M_2 \), \( C \) is the \( 4 \times 1 \) real matrix depends on a real parameter \( t \), \( X \) and \( X_0 \) are the position vectors of any point at \( \mathbb{R}^{4}_{\alpha\beta} \) respectively in \( R \) and \( R_0 \).

**Theorem 5.9.** The equation given by (5.11) determines a homothetic motion on \( M_2 \).

**Proof.** Since the curve \( \gamma \) is on \( M_2 \), it does not pass through the origin. So, the matrix given by (5.10) can be expressed as:

\[ B = M_\gamma(t) = h \begin{bmatrix} \gamma_1(t) & -\alpha\gamma_2(t) & -\beta\gamma_3(t) & \alpha\beta\gamma_4(t) \\ \gamma_2(t) & \gamma_3(t) & -\beta\gamma_4(t) & -\beta\gamma_4(t) \\ \gamma_3(t) & -\alpha\gamma_2(t) & \gamma_1(t) & -\alpha\gamma_2(t) \\ \gamma_4(t) & \gamma_4(t) & \gamma_4(t) & \gamma_1(t) & \gamma_2(t) & \gamma_3(t) & \gamma_4(t) \end{bmatrix} = hA, \]

where \( h : I \subset \mathbb{R} \to \mathbb{R}, t \to h(t) = \|\gamma(t)\| = \sqrt{\gamma_1^2 - \alpha\gamma_2^2 + \beta\gamma_3^2 - \alpha\beta\gamma_4^2} \). Since \( \gamma(t) \in M_2 \), \( \gamma_1(t)\gamma_2(t) + \beta\gamma_3(t)\gamma_4(t) = 0 \). By using this equality, we obtain that the matrix \( A \) given by (5.12) is a real quasi-orthogonal matrix. In that case it satisfies \( B^T \varepsilon B = \varepsilon \) and \( \det A = 1 \), where \( \varepsilon \) is the signature matrix corresponding to metric \( g_2 \) given by

\[ \varepsilon = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & \alpha \\ 0 & -\alpha & 0 & 0 & 0 & \beta & 0 & 0 \\ 0 & 0 & \beta & 0 & 0 & 0 & -\alpha & 0 \end{bmatrix}. \]

Hence \( A, h \), and \( C \) are real quasi-orthogonal matrix, the homothetic scale of the motion and the translation vector, respectively. So the equation (5.11) determines a homothetic motion.

**Remark 5.2.** The norm of the curve \( \gamma \in \mathbb{R}^{4}_{\alpha\beta} \) is found as

\[ \|\gamma(t)\| = \sqrt{\gamma_1^2 - \alpha\gamma_2^2 + \beta\gamma_3^2 - \alpha\beta\gamma_4^2}. \]

We assume that \( \gamma_1^2 - \alpha\gamma_2^2 + \beta\gamma_3^2 - \alpha\beta\gamma_4^2 > 0 \) in this paper.

**Corollary 5.5.** Let \( \gamma(t) \) be a curve on \( M_2^* \). Then one-parameter motion on \( M_2 \) given by (5.11) is a general motion consists of a rotation and a translation.

**Proof.** We assume that \( \gamma(t) \) is a curve on \( M_2^* \). Then \( \gamma_1^2 - \alpha\gamma_2^2 + \beta\gamma_3^2 - \alpha\beta\gamma_4^2 = 1 \). In that case the matrix \( B \) in (5.11) becomes a real quasi-orthogonal matrix, that is, it satisfies \( B^T \varepsilon B = \varepsilon \) and \( \det B = 1 \). This completes the proof.

**Theorem 5.10.** Let \( \gamma(t) \) be a unit velocity curve and its tangent vector \( \dot{\gamma}(t) \) be on \( M_2 \). Then the derivative of the matrix \( B \) is a real quasi-orthogonal matrix.
Proof. We suppose that $γ(t)$ be a unit velocity curve then $\dot{γ}_1^2 - α\dot{γ}_2^2 + β\dot{γ}_3^2 - αβ\dot{γ}_4^2 = 1$. Also since the tangent vector of the curve $γ$ is on $M_2$, we have $\dot{γ}_1(t)\dot{γ}_2(t) + β\dot{γ}_3(t)\dot{γ}_4(t) = 0$. Thus $B^TεB = ε$ and det $B = 1$. \hfill\Box

Theorem 5.11. Let $γ(t)$ be a unit velocity curve and its tangent vector $\dot{γ}(t)$ be on $M_2$. Then the motion is a regular motion and it is independent of $h$.

Proof. From Theorem 5.10, det $B = 1$ and thus the value of det $B$ is independent of $h$. \hfill\Box

Theorem 5.12. Let $γ(t)$ be a unit velocity curve whose the position vector and tangent vector are on $M_2$. Then the pole points of the motion given by (5.11) are $X_0 = -B^{-1}C$.

Proof. Since the position vector of the curve $γ$ is on $M_2$, from Theorem 5.9, the equation (5.11) becomes a homothetic motion. Also, because of $γ(t)$ is a unit velocity curve and $\dot{γ}(t) \in M_2$, from Theorem 5.10 det $B = 1$ and it implies that there is only one solution of the equation (4.1). Then the pole points of the motion given by (5.11) are found as $X_0 = -B^{-1}C$. \hfill\Box

Corollary 5.6. Let $γ(t)$ be a unit velocity curve whose the position vector and tangent vector are on $M_2$. The pole point associated with each $t$- instant in $R_0$ is the rotation by the matrix $B^{-1}$ of the speed vector of translation vector at the opposite direction $(-C)$.

Proof. From Theorem 5.10, the matrix $B$ is a real quasi-orthogonal matrix. Then the matrix $B^{-1}$ is quasi-orthogonal matrix, too. This completes the proof. \hfill\Box

Now we will give various examples of the homothetic motions on $M_2$ according to the situations of real numbers $α$ and $β$.

Example 5.4. For $α = β = 1$, $M_2$ becomes a hypersurface in $R^4_2$. Let $γ : I ⊂ R → M_2 ⊂ R^4_2$ be a curve as:

\begin{equation}
γ(t) = h(t) \begin{pmatrix}
cosh (at) \cos (bt) - \sin (at) \sin (bt) \ i \\
+ \cos (at) \sin (bt) \ j + \sin (at) \cos (bt) \ ij
\end{pmatrix},
\end{equation}

where $a$ and $b$ are real numbers. By using (5.10) and (5.13), the matrix $B$ is a homothetic matrix and $h : I ⊂ R → R$ is a homothetic scale. Also, for $h(t) = 1$, the matrix $B$ becomes a rotation matrix in $R^4_2$.

Example 5.5. For $α = -1$, $β = 1$, $M_2$ is a hypersurface in $R^4$. Let us consider the curve $γ : I ⊂ R → M_2 ⊂ R^4$ as follows:

\begin{equation}
γ(t) = h(t) \begin{pmatrix}
\cos (at) \cos (bt) - \sin (at) \sin (bt) \ i \\
+ \cos (at) \sin (bt) \ j + \sin (at) \cos (bt) \ ij
\end{pmatrix},
\end{equation}

where $a$ and $b$ are real numbers. From (5.10) and (5.14) we obtain the matrix representation of the curve $γ$ and it determines a homothetic matrix, in here $h : I ⊂ R → R$ is a homothetic scale. Also, for $h(t) = 1$, $γ$ becomes a spherical curve on $M_2$, that is, $γ(t) ∈ M_2^3 = M_2 ∩ S^3$. From Corollary 5.5, the matrix representation of it is a rotation matrix in $R^4$. 

\textcopyright F. Kahraman Aksoyak, S. "Ozkaldı Karakuš
Example 5.6. For \( \alpha = \beta = -1 \), the hypersurface \( M_2 \) becomes a subset of \( \mathbb{R}^2_4 \) and the following curve lies on \( M_2 \)

\[
\gamma(t) = h(t) \begin{pmatrix}
\cosh(at) \cosh(bt) + \sinh(at) \sinh(bt) i \\
+ \cosh(at) \sinh(bt) j + \sinh(at) \cosh(bt) ij
\end{pmatrix},
\]

in which \( a \) and \( b \) are real numbers. From (5.10) and (5.15), the matrix \( B \) according to the curve \( \gamma \) is a homothetic matrix, where \( h : I \subset \mathbb{R} \to \mathbb{R} \) is a homothetic scale. Also, if we take as \( h(t) = 1 \), then \( \gamma \) lies on \( M^*_2 \) and the matrix \( B \) gives a rotation matrix in \( \mathbb{R}^2_4 \).

5.3. Homothetic Motion on Hypersurface \( M_3 \)

Let us consider the hypersurface \( M_3 \) as follows:

\[
M_3 = \{ x = (x_1, x_2, x_3, x_4) \in \mathbb{R}^4_{\alpha \beta} : x_1 x_4 - x_2 x_3 = 0, x \neq 0 \}\.
\]

By using generalized bicomplex numbers, \( M_3 \) can be rewritten as:

\[
M_3 = \{ x = x_1 + x_2 i + x_3 j + x_4 ij \in \mathbb{R}^4_{\alpha \beta} : x_1 x_4 - x_2 x_3 = 0, x \neq 0 \},
\]

or the hypersurface \( M_3 \) can be expressed by using the matrix representation of generalized bicomplex numbers

\[
\tilde{M}_3 = \begin{pmatrix}
x_1 & -\alpha x_2 & -\beta x_3 & \alpha \beta x_4 \\
x_2 & x_1 & -\beta x_4 & -\beta x_3 \\
x_3 & -\alpha x_4 & x_1 & -\alpha x_2 \\
x_4 & x_3 & x_2 & x_1
\end{pmatrix} : x_1 x_4 - x_2 x_3 = 0, x \neq 0.
\]

where \( M_x \) is the matrix representation of generalized bicomplex number \( x \) on \( M_3 \). The metric on hypersurface \( M_3 \) is defined by \( g_3(x, x) = x \cdot x^{t_3} = x_1^2 + \alpha x_2^2 + \beta x_3^2 + \alpha \beta x_4^2 \) and the norm of any element \( x \) on \( M_3 \) is given by \( \| x \| = \sqrt{|g_3(x, x)|} = \sqrt{|x \cdot x^{t_3}|} \). This metric is Riemannian or pseudo-Riemannian metric on four dimensional generalized linear space \( \mathbb{R}^4_{\alpha \beta} \) and for some special cases, it coincides four dimensional Euclidean space \( \mathbb{R}^4_4 \) or four dimensional pseudo-Euclidean space \( \mathbb{R}^4_2 \).

Proposition 5.3. There are following properties about the norms on the hypersurface \( M_3 \).

i) For \( x, y \in M_3 \), \( \| x \cdot y \| = \| x \| \| y \| \)

ii) \( \| x \|^4 = \det (M_x) \)

Proof. These properties can be easily seen with direct calculations.

Corollary 5.7. A unit generalized bicomplex number on the hypersurface \( M_3 \) determines a rotation motion.

Proof. It is obvious from Proposition 5.3.
Theorem 5.13. $M_3$ is a commutative Lie group.

Proof. The proof can be found in [10]. □

Let us denote the set of unit generalized bicomplex number on $M_3$ by $M_3^*$. $M_3^*$ is given as:

$$M_3^* = \{ x \in M_3 : g_3(x, x) = 1 \} = \{ x \in M_3 : x_1^2 + \alpha x_2^2 + \beta x_3^2 + \alpha \beta x_4^2 = 1 \}.$$

Theorem 5.14. $M_3^*$ is Lie subgroup of $M_3$.

Proof. The proof can be found in [10]. □

Let $\gamma$ be a curve on $M_3$. In that case, it can be expressed as

$$\gamma : I \subset \mathbb{R} \rightarrow M_3 \quad t \rightarrow \gamma(t) = \gamma_1(t) + \gamma_2(t)i + \gamma_3(t)j + \gamma_4(t)ij,$$

$$\gamma_1(t)\gamma_4(t) - \gamma_2(t)\gamma_3(t) = 0.$$

Then the matrix $B$ corresponding to the curve $\gamma$ is given as follows:

$$B = M_3(\gamma(t)) = \begin{bmatrix} \gamma_1(t) & -\alpha \gamma_2(t) & -\beta \gamma_3(t) & \alpha \beta \gamma_4(t) \\ \gamma_2(t) & \gamma_1(t) & -\beta \gamma_4(t) & -\beta \gamma_3(t) \\ \gamma_3(t) & -\alpha \gamma_4(t) & \gamma_1(t) & -\alpha \gamma_2(t) \\ \gamma_4(t) & -\gamma_3(t) & \gamma_2(t) & \gamma_1(t) \end{bmatrix}. \quad (5.16)$$

Now by using this matrix $B$, we can define the one parameter motion on $M_3$ at $\mathbb{R}^4_{\alpha \beta}$.

Definition 5.3. Let $R_0$ and $R$ be the fixed space and the motional space at $\mathbb{R}^4_{\alpha \beta}$. In that case, the one-parameter motion of $R_0$ with respect to $R$ is denoted by $R_0/R$. Then the one-parameter motion on $M_3$ is given by

$$\begin{bmatrix} X \\ 1 \end{bmatrix} = \begin{bmatrix} B & C \end{bmatrix} \begin{bmatrix} X_0 \\ 1 \end{bmatrix},$$

or it can be expressed as

$$X = BX_0 + C, \quad (5.17)$$

where $B$ is the matrix associated with the curve $\gamma(t)$ on the hypersurface $M_3$, $C$ is the $4 \times 1$ real matrix depends on a real parameter $t$, $X$ and $X_0$ are the position vectors of any point at $\mathbb{R}^4_{\alpha \beta}$ respectively in $R$ and $R_0$, respectively.

Theorem 5.15. The equation given by (5.17) is a homothetic motion on $M_3$. 
Proof. Since the curve $\gamma$ is on $M_3$, it does not pass through the origin. So, the matrix given by (5.16) can be expressed as:

$$B = M_3(t) = \begin{bmatrix}
\frac{\gamma_1(t)}{h} & -\alpha\gamma_3(t) & -\beta\gamma_4(t) & \alpha\beta\gamma_3(t) \\
\frac{\gamma_2(t)}{h} & \frac{\gamma_3(t)}{h} & \frac{\gamma_4(t)}{h} & -\beta\gamma_3(t) \\
\frac{\gamma_3(t)}{h} & -\alpha\gamma_3(t) & \frac{\gamma_4(t)}{h} & -\beta\gamma_3(t) \\
\frac{\gamma_4(t)}{h} & \frac{\gamma_3(t)}{h} & \frac{\gamma_4(t)}{h} & \frac{\gamma_4(t)}{h}
\end{bmatrix} = hA,$$

where $h : I \subset \mathbb{R} \to \mathbb{R}$, $t \to h(t) = \|\gamma(t)\| = \sqrt{\gamma_1^2 + \alpha\gamma_2^2 + \beta\gamma_3^2 + \alpha\beta\gamma_4^2}$. Because of $\gamma(t) \in M_3$, we have $\gamma_1(t)\gamma_4(t) - \gamma_2(t)\gamma_3(t) = 0$. By using this equality, we obtain that the matrix $A$ in (5.18) is a real quasi-orthogonal matrix. In that case it satisfies $A^T\varepsilon A = \varepsilon$ and $\det A = 1$, where $\varepsilon$ is the signature matrix corresponding to metric $g_{\alpha\beta}$ given by

$$\varepsilon = \begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & \alpha & 0 & 0 \\
0 & 0 & \beta & 0 \\
0 & 0 & 0 & \alpha\beta
\end{bmatrix}.$$ 

Hence $A$, $h$ and $C$ are a real quasi-orthogonal matrix, the homothetic scale of the motion and the translation vector, respectively. So the equation (5.17) determines a homothetic motion.

Remark 5.3. The norm of the curve $\gamma \in \mathbb{R}_{\alpha\beta}^4$ is found as $\|\gamma(t)\| = \sqrt{\gamma_1^2 + \alpha\gamma_2^2 + \beta\gamma_3^2 + \alpha\beta\gamma_4^2}$. We assume that $\gamma_1^2 + \alpha\gamma_2^2 + \beta\gamma_3^2 + \alpha\beta\gamma_4^2 > 0$ in this paper.

Corollary 5.8. Let $\gamma(t)$ be a curve on $M_3^2$. Then one-parameter motion on $M_3$ given by (5.17) is a general motion consists of a rotation and a translation.

Proof. We assume that $\gamma(t)$ is a curve on $M_3^2$. Then $\gamma_1^2 + \alpha\gamma_2^2 + \beta\gamma_3^2 + \alpha\beta\gamma_4^2 = 1$. In that case the matrix $B$ given by (5.16) becomes a real-quasi orthogonal matrix, that is, it satisfies $B^T\varepsilon B = \varepsilon$ and $\det B = 1$. This completes the proof.

Theorem 5.16. Let $\gamma(t)$ be a unit velocity curve and its tangent vector $\dot{\gamma}(t)$ be on $M_3$. Then the derivative of the matrix $B$ is a real quasi-orthogonal matrix.

Proof. We suppose that $\gamma(t)$ is a unit velocity curve. Then $\dot{\gamma}_1^2 + \alpha\dot{\gamma}_2^2 + \beta\dot{\gamma}_3^2 + \alpha\beta\dot{\gamma}_4^2 = 1$. Also since the tangent vector of the curve $\gamma$ is on $M_3$, we have $\dot{\gamma}_1(t)\dot{\gamma}_4(t) - \dot{\gamma}_2(t)\dot{\gamma}_3(t) = 0$. Thus $B^T\varepsilon B = \varepsilon$ and $\det B = 1$.

Theorem 5.17. Let $\gamma(t)$ be a unit velocity curve and its tangent vector $\dot{\gamma}(t)$ be on $M_3$. Then the motion is a regular motion and it is independent of $h$.

Proof. From Theorem 5.16, $\det \dot{B} = 1$ and thus the value of $\det \dot{B}$ is independent of $h$. □
Theorem 5.18. Let \( \gamma(t) \) be a unit velocity curve whose the position vector and tangent vector are on \( M_3 \). Then the pole points of the motion given by (5.17) are \( X_0 = -\tilde{B}^{-1} \tilde{C} \).

Proof. Since the position vector of the curve \( \gamma \) is on \( M_3 \), from Theorem 5.15, the equation (5.17) is a homothetic motion. Also, because of \( \gamma(t) \) is a unit velocity curve and \( \dot{\gamma}(t) \in M_3 \), from Theorem 5.16 \( \det \tilde{B} = 1 \). Thus the equation (4.1) has only one solution. In that case the pole points of the motion are obtained as \( X_0 = -\tilde{B}^{-1} \tilde{C} \). \( \Box \)

Corollary 5.9. Let \( \gamma(t) \) be a unit velocity curve whose the position vector and tangent vector are on \( M_3 \). The pole point associated with each t- instant in \( R_0 \) is the rotation by the matrix \( \tilde{B}^{-1} \) of the speed vector of translation vector at the opposite direction \( (-\tilde{C}) \).

Proof. From Theorem 5.16, the matrix \( \tilde{B} \) is a real quasi-orthogonal matrix. Then the matrix \( \tilde{B}^{-1} \) is quasi-orthogonal matrix, too. This completes the proof. \( \Box \)

Now we will give various examples of the homothetic motions on \( M_3 \) according to the situations of real numbers \( \alpha \) and \( \beta \).

Example 5.7. For \( \alpha = \beta = 1 \), \( M_3 \) becomes a hypersurface in four dimensional Euclidean space \( \mathbb{R}^4 \). Let \( \gamma : I \subset \mathbb{R} \rightarrow M_3 \subset \mathbb{R}^4 \) be a curve as:

\[
\gamma(t) = h(t) \left( \begin{array}{c}
\cos(at) \cos(bt) + \cos(at) \sin(bt) i \\
+ \sin(at) \cos(bt) j + \sin(at) \sin(bt) ij
\end{array} \right),
\]

where \( a \) and \( b \) are real numbers. By using (5.16) and (5.19), the matrix \( B \) associated with the curve \( \gamma \) is a homothetic matrix, where \( h : I \subset \mathbb{R} \rightarrow \mathbb{R} \) is a homothetic scale. Also, if we take as \( h(t) = 1 \), then \( \gamma \) is a curve on \( M_3^* \). In that case it becomes a spherical curve lies on \( M_3 \) and the matrix \( B \) becomes a rotation matrix in \( \mathbb{R}^4 \).

Example 5.8. For \( \alpha = 1, \beta = -1 \), \( M_3 \) is a hypersurface in four dimensional Euclidean space \( \mathbb{R}^4 \). Let \( \gamma : I \subset \mathbb{R} \rightarrow M_3 \subset \mathbb{R}^4 \) be a curve given by

\[
\gamma(t) = h(t) \left( \begin{array}{c}
\cosh(at) \cos(bt) + \cosh(at) \sin(bt) i \\
+ \sinh(at) \cos(bt) j + \sinh(at) \sin(bt) ij
\end{array} \right),
\]

where \( a \) and \( b \) are real numbers. By using (5.16) and (5.20), the matrix representation of the curve \( \gamma \) is a homothetic matrix, in here \( h : I \subset \mathbb{R} \rightarrow \mathbb{R} \) is a homothetic scale. Also, for \( h(t) = 1 \), \( \gamma \) becomes a spherical curve on \( M_3 \), that is, \( \gamma(t) \in M_3^* \). The matrix representation of it is a rotation matrix in \( \mathbb{R}^4_2 \).

Example 5.9. For \( \alpha = \beta = -1 \), the hypersurface \( M_3 \) is in four dimensional pseudo-Euclidean space \( \mathbb{R}^4_2 \) and the following curve lies on \( M_3 \)

\[
\gamma(t) = h(t) \left( \begin{array}{c}
\cosh(at) \cosh(bt) + \cosh(at) \sinh(bt) i \\
+ \sinh(at) \cosh(bt) j + \sinh(at) \sinh(bt) ij
\end{array} \right),
\]

in which \( a \) and \( b \) are real numbers. From (5.16) and (5.21), the matrix \( B \) according to the curve \( \gamma \) is a homothetic matrix, where \( h : I \subset \mathbb{R} \rightarrow \mathbb{R} \) is a homothetic scale. Also, if we take as \( h(t) = 1 \), then \( \gamma \) lies on \( M_3^* \) and the matrix \( B \) gives a rotation matrix in \( \mathbb{R}^4_2 \).
REFERENCES
