PP98. Comparison of the essential-oil composition of *Salvia sclarea*
L. aromatherapy oils from Turkish markets

Hilmi Tuğkan Gülen¹**, Yasemin Yücel Yücel², Kaan Polatoğlu³

Keywords: essential oil, *Salvia sclarea*, AChE, aromatherapy oils

*Salvia officinalis* does not find a natural habitat in Turkey, however, it is cultivated mostly for export. On the other hand, *Salvia fruticosa* and *S. sclarea* are gathered from wild-growing populations, cultivated, used and sold instead of *S. officinalis* for various purposes in Turkey. Previously, the essential-oil composition of *S. sclarea* from various countries was investigated and samples containing linalyl acetate, linalool, germacrene D, α-terpineol, neryl acetate, geraniol, geranyl acetate, nerol, and sclareol were reported [1,2]. In contrast, the essential oil of *S. fruticosa* was reported to contain α-pinene, β-piine, 1,8-cineole, β-myrcene, and camphor as the main components [3]. In the current study, one aromatherapy-grade essential-oil sample was acquired from a pharmacy and another from a herb shop. Additionally, *clary sage* (adaçayı – local name) was bought from a herb shop and the plant material was used to obtain an essential-oil sample by hydrodistillation using a Clevenger apparatus in the duration of 3 h. The essential oils were analyzed on the Agilent 5977 MSD GC-MS system. The main components of the oil obtained by hydrodistillation were 1,8-cineole (26.8%), camphor (8.9%), α-pinene (6.4%), β-pinene (6.3%), and β-caryophyllene (5.2%). The aromatherapy oil bought from the herb shop contained 1,8-cineole (32.6%), β-caryophyllene (8.7%), camphor (7.3%), α-pinene (6.5%), and β-pinene (5.8%). The aromatherapy oil and the oil obtained from the plant sample sold as *clary sage* had a composition that is similar to that of *S. fruticosa* essential oil. The aromatherapy oil acquired from a pharmacy shop, which is sold as an imported product, contained linalyl acetate (52.1%) and linalool (20.0%) the presence of which is indicative of *S. sclarea* (clary sage) oil. The essential oils were also investigated for their AChE-inhibitory properties. The best noted inhibitory properties of the aromatherapy oil and the hydrodistilled oil were 99±1% and 99.8±0.4%, respectively; whereas the oil sample from pharmacy shop at the same concentration reached the inhibition of 13±2% (n = 3). The results clearly indicate that the products sold as *S. sclarea* on the Turkish market show a great variation due to the misuse of (adulteration with) *S. fruticosa*. This study clearly reveals that further legislation and control is required on the Turkish herbal market in order to protect and inform consumers.
